COVER PHOTO: A typical village in the deeply flooded area of the Northeast Region. The earthen village platform is created to keep the houses above water during the flood season which lasts for five to seven months of the year. The platform is threatened by erosion from wave action; bamboo fencing is used as bank protection but often proves ineffective. The single *hijal* tree in front of the village is all that remains of the past lowland forest. The houses on the platform are squeezed together leaving no space for courtyards, gardens or livestock. Water surrounding the platform is used as a source of drinking water and for waste disposal by the hanging latrines. Life in these crowded villages can become very stressful especially for the women, because of the isolation during the flood season. The only form of transport from the village is by small country boats seen in the picture. The Northeast Regional Water Management Plan aims to improve the quality of life for these people.

#### D.1 Introduction

The Flood Action Plan (FAP 6) comprises a number of studies and pilot projects which are expected to lead to water resources management and related projects with an emphasis on flood control and drainage. The Northeast Regional Water Management Project (NERP) is at a critical phase where project impacts on the resource base, social groups, ecology and environment require a financial and economic appraisal to be conducted for selected projects prior to making an investment decision. The Dampara Water Management Project has been identified as a priority investment project and, accordingly, rigorous project appraisal techniques are required to determine its economic feasibility and to assess expected impacts on the resource base and the environment.

The economic evaluation or cost-benefit analysis is a key element in the appraisal stage of the project cycle. Cost-benefit analysis (CBA) is used in this report to assess the economic viability of the Dampara Water Management Project (DWMP). The economic analysis using CBA techniques ensures the most economically efficient use of scarce resources by identifying those projects or project components which offer the highest economic rate of return on an investment. Policy-makers and investors alike must be particularly cognisant regarding the investment of scarce capital resources that will best further national objectives. This is true whether the resources committed are being invested by the government directly or by individuals within the economy.

# D.2 Methodology

The Guidelines for Project Assessment have been produced by the FPCO with the aim of standardising the methodology and assumptions applied in the economic analysis undertaken by different FAP studies. They are based on widely accepted techniques for the appraisal of water resource development projects and provide a good basis for achieving the necessary degree of uniformity and comparability between FAP studies. This study used the FPCO Guidelines for Project Assessment (May 1992) which outlines the detailed costing procedures for capital, operation and maintenance (O&M) costs; market and economic prices to be used; and areas for which benefits/disbenefits are to be analysed. For comparative purposes and to avoid inflationary distortions, all prices and costs are converted to the price level typical of 1991. The FPCO Guidelines also discuss the phasing of benefits, mitigation measures to be taken, the period of analysis, and the rate by which the cost-benefit stream is to be discounted. The FPCO Guidelines also illustrates a multi-criteria analysis which provides a comprehensive basis for a comparison of expected impacts in economic, quantitative and qualitative terms.

This study is largely based on NERP longitudinal and cross-sectional data series and supported by NERP hydrological information. The basis of the subsequent economic analysis was the construction of a computer spreadsheet model developed by NERP simulating the expected benefit/cost streams emanating from the with (FW) and without (FWO) situations extending over a 30-year period after project construction is initiated. The economic decision criteria employed are 'Net Present Value and Economic Internal Rate of Return'.

## Net Present Value (NPV)

'Net Present Value' is the sum of the discounted incremental net cash flow stream of the project. It is the cumulative present worth of the incremental national income generated by the investment. For a project to be economically feasible, the NPV must be positive for a pre-determined discount rate which reflects the opportunity cost of capital in Bangladesh (=12%/annum excluding inflation).

# Economic Internal Rate of Return (EIRR)

The discount rate which when applied to the stream of incremental benefits and costs as reflected in the net cash flow of a project produces a zero net present value. It is the maximum (real, non-inflationary) annual rate of interest that a project could pay for the resources used if the project is to recover all its costs and still break even. For a project to be economically feasible, the EIRR must be equal or greater than the opportunity cost of capital (or "cut-off rate") in Bangladesh, i.e. > 12%/annum, excluding inflation.

These are estimated on the basis of projected annual incremental net costs and benefit streams from the *future with* (FW) and *future without* (FWO) situations; all expressed in terms of constant (1991) costs and prices. "Economic" costs and prices are synonymous with efficiency prices or undistorted international price levels, exclusive of all taxes and subsidies. They are sometimes called "shadow" prices or "border" prices. The appropriate economic conversion factors are provided in FPCO *Guidelines for Project Assessment* (May 1992).

Additionally, sensitivity analyses are conducted to measure the reliability and robustness of estimates, and to identify the benefit and cost items which have the greatest influence on the overall economics of the project.

The specific impacts which have been quantified in the economic analysis following are:

- agricultural production and employment
- captured and cultured fisheries production
- protection of socio-economic infrastructure
- navigation
- agro-forestry and wetland resources

# D.3 Future With (FW) and Future Without (FWO) Comparisons

Project assessment requires the estimation of incremental benefit and cost streams over the economic life of the project. That is, project analysis tries to identify and value all the quantifiable costs and benefits that will arise with the proposed project and to compare them with the situation as it would be without the project. The difference is the incremental net benefit arising from the project investment. This approach accounts for changes in production that would occur without the project.

The without project planning scenario covers the same 30-year period as the with project scenario and assumes that no other publically financed major flood control and drainage measures are undertaken during the period. In the FW project situation, an embankment is proposed along the right bank of the Kangsha River to provide flood protection to the project area. The embankment would be designed to give protection against monsoon floods of 1:20 year return period. The proposed embankment would connect to the existing BWDB embankment at Jaria. As a result of

the flood protection measures, the depth of flooding will be reduced and the area of flood-free land will be increased. The total physical area impacted would be about 15,000 hectares (Table D.1).

Table D.1

Land Use Pattern: Present, FWO and FW Situations (hectares)

Land Use	Present Use	FWO Use	FW Use
Net Cultivated Area	12,525	12,377	12,292

Total	15,000	15,000	15,000

Source: Annex B (Agriculture), Table 7.1

#### D.4 Cost Estimation

# D.4.1 Capital Cost

Cost estimating procedures are detailed in the FPCO *Guidelines*. As given in the table in the following page, the estimated total capital costs are Tk 64.2 million (1995 prices) inclusive of land acquisition costs, mitigation costs, and enhancement programme costs.

Excluded from the economic analyses following are:

Land Acquisition Costs : Tk 20.5 million Enhancement Programme Costs : Tk 3.9 million

Land acquistion costs of Tk 20.5 million (see Appendix Table 1) are excluded from the economic analysis because land taken out of production by the proposed project is valued in terms of production foregone. Environmental enhancement costs are excluded because an offsetting monetary estimate of the benefits from such an investment was not calculated. Environmental mitigation costs are included in the capital cost summary even though it is similarly true that post-mitigation impacts are not estimated. This may introduce a slight downward bias into the benefit-cost analysis conducted following.

Physical contingencies equal to 15 percent of base construction costs as per FPCO 'Guidelines were used to cover unforeseen costs. Engineering design and supervision costs were computed as 9 percent of base construction costs and physical contingencies.

Capital costs were then deflated to June 1991 constant prices using the appropriate Bangladesh Bureau of Statistics construction price index. (Deflator = .875) FPCO -determined conversion factors (see 'Guidelines) were subsequently used to convert the market cost estimates into economic cost estimates. Total capital costs considered in the economic analysis in 1991 constant economic prices are estimated to be 25.8 million Taka, scheduled to be dispersed as follows:

Year 1 Tk. 852,000
Year 2 Tk 11,622,000
Year 3 Tk 13,317,000
Tk 25,791,000

Detailed quantity and cost estimates are provided in Annex A (Engineering) and Annex E (Environmental Impact Assessment).

Ca	pital Cost Summary ('000 Tk)	
Type	Item	1995 Price
FCD Interventions	Embankments	16,294
	Structures	3,524
	Channel	1,302
	Closure & Diversion Channel	866
	Sub-Total	21,986
Mitigation Measures	Fisheries	2,000
	Wetland & Wildlife	400
	Homestead Raising	2,940
	Sub-Total	5340
Enhancement Programme	Agriculture	400
	Fisheries	1,000
	Social	2,000
	Sub-Total	3,400
Land		20,500
	Total	51,226
	Physical Contingencies (15% of total)	7,684
	Sub-Total	58,910
	Study Cost (9% of Sub-Total)	5302
	Grand Total	64,212

#### D.4.2 O&M Costs

Again following the FPCO 'Guidelines for Project Assessment (May 1992), Operation & Maintenance (O&M) costs have been calculated as a percentage of capital costs: 6 percent for embankments and drainage channels, 3 percent for structures, and 5 percent for other costs. Homestead raising does not have any O&M cost associated with it. Physical contingencies equal to 15 percent of O&M costs are then added to the sub-total to obtain the total estimated O&M cost per year. O&M costs are expected to amount to about Tk. 1.17 million by Year 3 and Tk. 1.79 million/year during Years 4 through 30 (Appendix Table 1).

# D.4.3 Phasing & Disbursement

Three years are required to implement the proposed project. Cadastral surveys, topographic surveys, detailed engineering design as well as preparation of tender documents and awarding of contract would be carried out in Year 1. Land acquisition must be completed prior to the start of construction. Construction would start in Year 2 and should be completed in Year 3. The implementation of the mitigative measures would also start in Year 2 and continue into Year 3. There would not be any payback to the project until Year 4.

#### D.4.4 Benefits & Disbenefits

The principal direct benefits is the projected increase in agricultural production in the project area while supplementary benefits are due to a reduction in damages in public infrastructure, commercial and agricultural assets, fish ponds, homestead plantations and agro-forestry. Substantial indirect benefits will also be realized by the World Bank/IDA Kangsha River Project through the flood protection afforded. The main disbenefits come from expected losses to the floodplain fishery resource along with navigation and wetland resource losses. These are discussed in detail under the following respective sub-headings:

- D.5 Agriculture
- D.6 Fisheries
- D.7 Socio-Economic Infrastructure
- D.8 Navigation
- D.9 Homestead Gardens, Agro-Forestry & Wetland Resources

# D.5 Agriculture

#### D.5.1 Anticipated Benefits

The major benefits expected from the proposed project relate to increased crop production. This would largely arise through less direct flood damage to crops, as well as the substitution of local rice varieties for HYV rice for planting during the monsoon season. That is to say, with improved flood control, two major crop production changes are expected:

- the proportion of damage-free land versus flood-damaged land increases; thus
  increasing average crop yields and output for any and all cropping patterns; and,
- the cropping pattern will shift in favour of higher-yielding crops, particularly HYV rice production

Growing the shorter HYV rice becomes increasingly feasible when the risk of flooding decreases and the window available for re-planting during the monsoon season increases. (For additional details, see Annex B (Agriculture)).

# D.5.2 Market & Economic Shadow Prices

The analysis uses the FPCO 'Guidelines which indicates both market prices and economic shadow prices for agricultural products as well as agricultural production inputs. These prices are designated 1991 constant prices to be employed in all FAP Planning studies. (See attached Appendix Tables 2 & 3).

# D.5.3 Present & Without Project (FWO) Crop Yields

It has been assumed that overall yields under flood free conditions will increase for spices, vegetables, oilseeds and wheat as indicated in the past ten years' national trend (re: Statistical Yearbook of Bangladesh, Bangladesh Bureau of Statistics, various years). Since these yield increases are not due to the implementation of the project, however, they are the same for both the without project (FWO) and with-project (FW) situations. The proposed project will not have any impact on these yield changes. It is assumed that the remaining crop yields—including all rice crops and sugarcane—will remain constant in the present and FWO situations (see Table D.2). However, the average yields representing the weighted average of the yields in flood-free and flood-damaged land are not the same for the present and FWO situations. This is because some changes are expected in the damage-free areas in the FWO situation (Table D.2).

For the with-project (FW) situation, average overall yields effectively increase for all rice crops because of the expected reduction in the rice area flooded, as well as the opportunity to shift to more HYV rice. For all other crops, the yield levels are considered to be the same for both the FWO and FW situations, as also illustrated in Table D.2.

Yield estimates for Damaged Crop areas were estimated through a Farm Household Survey. These estimates generally range from 50 to 75 percent of undamaged crop yields.

## D.5.4 Cropping Pattern

For the FWO situation, a review of the recent flood frequency and Bangladesh Bureau of Statistics (BBS) annual crop production data show that crop losses will continue to increase in the Kharif II monsoon season. Flood damage would be expected to affect local transplanted aman (t. aman) and decrease the *present* crops in F<sub>3</sub> lowland areas by about 2.0 percent.

To project cropping patterns after project implementation, the area in each land type was reestimated according to post-project flood depth and then adjusted for the crops currently grown on each type of land. Land types are defined in terms of monsoon flood depth:

Land Type	Flood Depth (m.)
Fo	0.0 - 0.3
F1	0.3 - 0.9
F2	0.9 - 1.8
F3	>1.80

Using this general procedure (as detailed in Annex B - Agriculture), it is expected that cropping patterns would change quite considerably as a result of, in particular, increased flood protection in the Kharif II monsoon season. Flood protection would permit more timely planting of aman rice and allow farmers to replace low-yielding traditional varieties with HYV transplanted aman during the monsoon season. It is likely that farmers will adopt these more intensive cultivation practices due to reduced risk from flood damage in the Kharif II monsoon season. It is expected that the total area cropped/calender year will also increase slightly, as the cropping intensity climbs from 194 percent to a projected 202 percent in the FW project situation.

These simulations are provided in Appendix Tables 4, 5, and 6.

Source: Imputed from Appendix Tables 7,8 and 9.

# D.5.5 Total Production & Revenue: Main & By-Product

Estimated cropping patterns (i.e. areas) together with estimated yields for the *present*, FWO, and FW situations allow the project analysts to estimate production levels for each crop (see Appendix Tables 7, 8 and 9). Additionally, the FPCO *Guidelines* indicate the amount of by-product (e.g., rice straw, wheat straw, etc.) produced per unit of main product (see Appendix Table 2).

The gross revenue earned from each crop is derived from both the main product and its by-product and is given by:

Gross Revenue = Area x Yield x Price

where prices are expressed in terms of both market prices and economic prices (See above). Table D.3 shows the total estimated gross revenue earned for each crop under the three different scenarios (i.e. present, FWO and FW) using both market and economic prices. Per-hectare estimates are provided in Appendix Tables 10 and 11.

# D.5.6 Crop Input Use & Cost of Production

Per -hectare input requirements have been estimated for each crop for the *present*, FWO and FW situations (see Appendix Tables 12, 13 and 14). The *present* scenario is intended to represent typical existing (not recommended) input levels which are commensurate with the corresponding yield levels recorded. The production inputs considered include labour, fertilizer (i.e., nitrogen, phosphorous and potassium but excluding minor nutrient elements—sulphur, zinc, magnesium, etc.), traditional and modern irrigation methods, draught animal use (there was no power tiller use reported in the project area), seed and pesticide.

The total cost-of-production estimates for the *present*, FWO and FW situations are calculated as follows:

Cost = Per-Hectare Input Requirements x Area x Unit Input Prices
[Appendix Tables 12,13,14] x [Appendix Tables 4,5,6] x [Appendix Table 3]

Prices are again expressed in terms of both market prices and economic (or shadow) prices. In addition, the financial (market) analysis includes some costs which are excluded from the economic analysis. These are loan interest on working capital and miscellaneous expenses. Loan interest is taken out of the economic calculations because they are considered a transfer payment (to capital) within the nation. Loan interest is included in the financial analysis at an interest rate of 17.5 percent per year for a six month period on 80 percent of cash costs of production for each crop. The miscellaneous expenses are assumed to be 10 percent of the cash costs and the loan interest. The resulting total costs of production using both market and economic prices under different scenarios are shown in Table D.4 below.

# D.5.7 Net Margin & Net Incremental Benefit

The estimated net margin for each crop is determined by subtracting the total cost- of- production from the gross revenue earned:

Since all labour costs (including family labour) are included in the respective Cost-of-Production estimates, this is essentially a net return to capital and management. This is sometimes termed a gross profit margin or, in benefit-cost analyses, the net benefit.

The net incremental benefit attributable to the proposed project is, therefore, given as:

Net Incremental Benefit = Net Benefit FW - Net Benefit FWO

In public benefit-cost analyses, it is the economic net incremental benefit which is of particular concern. All of the net benefit calculations, as well as the net incremental economic benefits, by crop, are summarized in Table D.5 following. These calculations indicate that at project maturity the project should generate an average annual net incremental benefit of about Tk. 43.5 million per year. This translates into an average of about Tk. 3500/physical ha./year; a relatively large annual benefit.

Table D.5

# D.5.8 Impacts

The agricultural sector will realize the largest impact from the project, mostly from increases in aman crop production during the Kharif II monsoon season. In the monsoon season, benefits will be achieved in the FW project situation due to: i) gains from earlier (i.e., more timely) planting of late (LT) and HYV Aman; ii) intensification of production by switching from broadcast and local transplanted LT aman to HYV aman rice varieties; and, iii) higher long term overall average yields due to reduced flood losses. In the rabi season, improved drainage may protect the irrigated boro crop from damage and facilitate crop intensification through more extensive cultivation of boro rice and rabi season crops. In addition, young aus seedlings will be protected from pre-monsoon rainfall run-off and waterlogging.

During the Kharif II season, crop production will increase by approximately 43 percent. The impact on rice production in the aus and rabi seasons is comparatively very low; production is expected to increase by about 1 percent in each season. However, the project will have considerable impact on the production of non-rice rabi crops which are expected to increase by nearly 47 percent. This increased crop diversification is also considered a benefit of the project.

The project is expected to increase rice crop production from 67,260 MT (FWO) to 77,200 MT FW or 9,942 MT (14.8 percent) and non-rice crop production from 3,544 MT to 5,022 MT or 1,478 MT (41.7 percent) per year. The cropping intensity increases by 4 percent from 1.94 to 2.02. It is also expected that the project will have a considerable impact on the adoption of HYV rice. The ratio of the area under local rice varieties to HYV rice is expected to change from a 60: 40 ratio to a 40: 60 ratio in the FW project scenario.

Additionally, the project will have a considerable impact on agricultural employment in the region. Due to increases in cropping intensity, the demand for labour per hectare of land should increase from an average of 126 to about 137 person days (or 8.7 percent) per annum. Total agricultural employment in the project area is expected to increase from 3.03 million person days to 3.41 million person days per year.

All of these calculations ignore the probability that some flooding is still going to occur, albeit rarely, because of both external (river-flooding) and internal (rainfall) events. To account for this likelihood, all of the preceding projections regarding production and employment should be deflated by about eleven percent (see Section D.5.9).

Additional details regarding the anticipated on-farm impacts are provided in Section D.11 following.

# D.5.9 Adjustments to Increased Agricultural Benefits

There are three required downward adjustments to the basic estimate of Tk. 43.49 million/year calculated previously. These are:

• The project is designed to give protection against (externally-generated) monsoon floods for a 1:20 year return period. Thus, it is probable that during the 30-year project period the entire crop might still be completely destroyed about 1.5 times. This is mathematically equivalent to a loss of about 5 percent of the incremental net benefit/annum.

- 5
- The drainage system has only been designed for a 1:5 year rainfall. This "internal event", therefore, will still generate additional flooding 20 percent of the time irrespective of the flood control measures here being considered. It is expected that this will effectively destroy about 30 percent of the crop affected in this manner. This is mathematically equivalent to about 6 percent of the incremental net benefit/annum.
- Thirdly, it is mandatory to account for the farm management adjustment process that will gradually take place after the project is operational. With improved flood control, farmers will only gradually adjust their crop production practices to take advantage of the new opportunities available to them. This is often referred to as the S-shaped adoption process. The FPCO *Guidelines* stipulate that we should expect full crop benefits to only be achieved by the end of Year 8. Incremental net benefits are expected to climb (linearly) 20 percent per year through Years 4,5,6,7,and 8.

These probabilistic and behavioural imperatives are not discretionary "adjustments" to the preceding calculations. They are inherent to the most-likely Base Case scenario, as summarized in Table D.6 following.

Table D.6
Simulated Annual Net Incremental Agricultural Benefit
Base Case - Final Estimate

	Annual Net Incremental Benefit				
	Rice (ton)	Non-Rice (ton)	Net Economic (mtk)	Employment (mpd)	
Non-Probabilistic Estimate	9,942	1,478	43.49	0.38	
Less Damage from Residual External Flood Probability (5%)	-497	-74	-2.18	-0.02	
Less Damage from Residual Internal Flood Probability (6%)	-597	-89	-2.61	-0.02	
Base Case - Annual Incremental Benefit	8848	1,315	38.70	0.34	

#### D.6 Fisheries

#### D.6.1 Market & Economic Prices

Wholesale market fish prices are taken from FAP 17 Fisheries Study and Pilot Project: Fish Marketing & Prices (June 1994). Market prices were deflated to 1991 constant prices as prescribed in the FPCO Guidelines. The Guidelines' standard conversion factor has been used to determine the economic prices (see Appendix Table 17).

Harvest costs have been determined for both the open-access capture and pond culture fisheries (again see Appendix Table 17). These costs have been taken as constant. This is not an entirely satisfactory approach because variable (i.e., direct) costs are inversely related to the amount of fish available for harvest; for instance, as fish stocks increase the variable cost declines and, as fish stocks decrease then the variable cost increases, reflecting the demand for more labour and gear resources to chase declining fish stocks. This marginal increase/decrease in harvest costs has not been reflected in the analysis.

# D.6.2 Habitat Areas & Production Parameters

The present, FWO and FW analysis is based on primary data collection efforts including the NERP "Fishing Effort Survey" and the "Catch Assessment Survey" which was conducted in the Dampara Project area over a twelve month period. The respective habitat areas (floodplain & beel, river, and culture ponds) and corresponding production parameters used in the subsequent analysis are given in Appendix Table 18.

#### Floodplain & Beel Fisheries

There has been a downward trend of between 3 to 5 percentage points per annum in relation to fisheries production for the open access common fisheries resources in Bangladesh. It has been assumed that this trend is likely to continue unless there are strong mitigation measures taken by the Government of Bangladesh. Consequently, in the FWO and FW situation, a steady decline of 3 per cent per year is expected for all land classes (F0 thru F3) for the duration of the project period (Year 30). The resulting estimates of fishery production per hectare for each land class over the 30 year period under FWO and FW conditions are given in Appendix Tables 19 and 20, respectively.

#### Riverine Fisheries

A downward trend in riverine fish production is also anticipated for both FWO and FW situation at a rate of 3 percentage points per annum over the 30 year life of the project (again see Appendix Tables 19 and 20).

# Cultured Pond Fisheries

There are presently 85.0 hectares of flood-free pond and 35.0 hectares of flood-prone pond culture fisheries in the Greater Dampara Project area. Following the present trend in the IDA-funded Kangsha River Project area, it is expected that there will be a gradual increase in "flood-free" pond culture fisheries during the next ten years under the FWO project situation. It is expected that the area of "flood-free" pond culture fisheries will gradually climb to 135 hectares over the next ten years. This would represent a 1.64 percent increase per annum (see Appendix Table 21).

Under the FW project scenario, all 35.0 hectares of flood-prone pond culture fisheries would become flood-free ponds by Year 4 of project implementation. A survey conducted in the IDA-funded Kangsha River Project area revealed that flood control interventions increased the total pond area by around 200 percent over a ten year period following project implementation. The project analysts expect a similar level of development to take place in the Dampara project area for the FW situation. Consequently, it has been assumed that there will be a 150 percent increase in flood-free pond area over a ten year period which will then stabilize at 180 hectares of flood-free pond culture fisheries by Year 14 of the FW project cycle. This would represent a 4.14 percent increase per annum from Year 4 - 14 and stabilizing in Year 14 (Appendix Table 21).

#### D.6.3 Fishery Production

Anticipated annual total production for each type of habitat for both the FWO & FW scenarios are obtained by multiplying the projected area under each habitat with the corresponding projected unit production levels for the respective habitat per hectare of area. Total production from open-access fisheries represents the aggregate of floodplain and beel production, and river production. Total production from cultured fisheries consists of production from both flood-free and flood-prone ponds. The incremental production represents the total expected change in fisheries production between FW and FWO (Appendix Table 22).

### D.6.4 Fishery Gross Revenue & Costs

Applying market and economic prices (Appendix Table 17) to the anticipated FW and FWO production situations (Appendix Table 22) yields the projected gross revenue generated from fisheries production (Appendix Table 23).

Production costs are calculated by multiplying the unit area costs (Appendix Table 17) by the respective fishery areas (Appendix Tables 19 to 22).

# D.6.5 Fishery Net Returns & Incremental Net Benefits/Disbenefits

Net returns are obtained by subtracting the harvest costs from total revenue (Appendix Table 23) and are given in Appendix Table 24. The annual incremental benefit (disbenefit) to fisheries is obtained by subtracting the projected net return for the FWO situation from that of the FW situation. These estimates for both captured and cultured fisheries are summarized in Table D.7.

# D.6.6 Impacts

The results show that the floodplain and beel fisheries production is reduced over the years in both the FW and FWO situations. (Appendix Table 23) However, in the FWO situation the reduction in production is due to an anticipated general decline of 3 percent per year in the fisheries resource (i.e., a trend reflected throughout Bangladesh) while in the FW scenario the loss in *open-access* fisheries is accentuated due to i) a contraction of feeding areas; and, ii) a shift towards more low -yielding fish habitat (i.e.,  $F_0$  land type, with < .30 meters of flood waters). In the *present* situation,  $F_2$  land areas return the highest catch per unit of effort (CPUE) but these areas will be reduced from 2,250 ha. to 603 ha. in the FW situation.  $F_0$  land areas which return the lowest CPUE in the *present* situation will increase from 6,000 ha. to 9,000 hectares. Anticipated changes in the respective *land areas* represent the main cause in the reduction of the fishery resource although, a reduction in the feeding area by 978 ha. is also a contributing factor.

Table D.7

30	-3.27	1.81	-1.46	-1.27

Source: Appendix Table 24

Conversely, the simulations indicate that there should be a net benefit accruing to pond culture fisheries as early as FW Year 4. This is due to the fact that all the 35 hectares of flood-prone ponds become flood-free ponds. Moreover, flood control interventions accelerate an increase in the pond area as noted in the IDA-funded Kangsha River project area. However, production gains from pond culture fisheries do not totally offset the substantial losses accruing to the open access captured fisheries resource base. The net result is that there will most likely be disbenefits in the fisheries sector from the first year of the implementation of the project (i.e., Year 3) which will continue throughout the economic life of the project.

# D.7 Non-Agricultural Infrastructure Benefit

In the present situation flood damage occurs not only to standing crops and livestock but also to stock resources. Flood damage to stock resources includes the following:

- damage to infrastructure (including roads, railways, bridges, culverts and hydraulic structures)
- damage to public and private buildings, houses and installations, including industrial and commercial premises, equipment and supplies.

## D.7.1 Data Sources

Data were collected from the Local Government & Extension Division (LGED), Department of Agricultural Extension/Ministry of Agriculture (DAE/MOA), Bangladesh Railway (BR), Bangladesh Water Development Board (BWDB) and Thana Union offices in the project area for the following years:

- i) 1988 with a probability of a 1:25 year return period);
- ii) 1991 with a probability of a 1:2 year return period;
- iii) 1993 with a probability of a 1:20 year return period; and
- iv) 1995 with a probability of a 1:10 year return period.

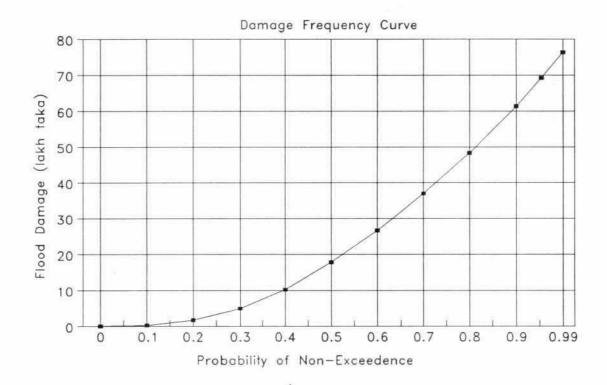

In a number of cases, however, flood damage data collected from GOB offices was found to be grossly inflated when compared with other secondary sources—including World Bank 1991 Cyclone Damage Report, Jamalpur Priority Project Study (January 1993), and NERP engineering information. Necessary adjustments were made where such inflated values were detected. Sectoral deflators published by the Bangladesh Bureau of Statistics (BBS) were then used to summarize all damage estimates in terms of constant 1991 prices. These estimates are summarized in Appendix Table 25.

The 1993 flood damage estimates were found to be very inconsistent with the expected 1:20 year estimates and therefore were not employed in the analyses conducted immediately following. This anomaly lies in the methodology. The main difficulty lies in attempting to assign a return period to the reference years which is based only on the level of water in the sample sites during flood. The complexity of the flood phenomenon and the multiplicity of the causes of damage—including depth of water in the rivers, discharges and water speed, local rainfall, duration of flood peaks, dates of occurrence of floods in the cropping calendar, etc.—are all reasons for the difficulty in conducting a statistical analysis of the flood damages in Bangladesh and elsewhere.

# D.7.2 Calculation of Mathematical Expectation of Damage

Flood damage data for the 1991, 1995 and 1988 year time series were used to determine the mathematical expectation of annual flood damage as per the FPCO *Guidelines*. The horizontal scale of Figure D.1 (see following) depicts the average frequency of occurrence, and the vertical scale gives the damage valuation in Taka. A smooth curve is drawn through these points and extended in both directions. This curve can be approximated by the use of a quadratic equation of the form  $y = a + bx + cx^2$  where y is the estimated flood damage, x is the average frequency of occurrence, and a, b, and c are the parameters to be estimated. An OLS regression was then run using the data available for 1991, 1995, and 1988 to estimate the respective parameters (Table D.8).

Figure D.1 Non-Agricultural Damage -Flood Frequency Curve

On this basis, it is then possible to estimate flood damage costs associated with different flood frequencies by substituting various frequency return periods into the estimated quadratic equation. These estimates are summarized in Column [3] of Table D.9 below and illustrated graphically in accompanying Figure D.1.

Year	y (flood damage)	x (Probability of Flood	x²
1991	19.51	0.50 (1:2 year)	0.25
1995	51.42	0.90 (1:10 year)	0.81
1988	79.16	0.96 (1:25 year)	0.92
Regression Output	Constant (a)	x coefficient (b)	x² coefficient (c)
	0.51	-10.14	86.70

# D.7.3 Value of Annual Non-Agricultural Flood Damage Protection Benefit

Integral calculus has been used to determine the surface area under the curve, as given by the cost and frequency differential values in Table D.9, Column [4]. The cumulative surface area (the summation of the values in Col. [4]) is indicated in Column [5].

The Dampara Water Management Project (DWMP) proposes construction of an embankment providing full-flood protection for a flood return period of 1:20 years (i.e., 95 per cent non-exceedance frequency). Further if it is assumed that only floods exceeding an average frequency of 0.5 (1:2 year return period) cause significant damage, then the surface area under the damage frequency curve between the frequencies 0.5 and 0.95 yield the mathematical expectation of annual damage. This is estimated to be equal to 1.95 million Taka/year (see Col. [5]).

It is expected that this will be the value of the annual non-agricultural flood damage protection benefit, beginning in Project Year 4. Thereafter, it is expected (according to the FPCO *Guidelines*) that this capital stock (and thus the damage incurred to this capital) would grow at an annual rate of approximately 3 percent per year for the duration of the economic life of the project, i.e. 30 years. These are the estimates utilized in the economic benefit-cost analysis conducted in Section D.10 following.

#### D.8 Navigation

The Kalihar Channel is the only navigational route in the Dampara Water Management Project (DWMP) area. The 1995 NERP "Boat Traffic Survey" indicated that approximately 1,060 metric tonnes of cargo are transported through this route.

The DWMP will close the Channel with a drainage regulator so that it will then be necessary to transfer cargo across this structure. The additional trans-shipment cost incurred is estimated to amount to a relatively modest Taka 26,500 per annum (i.e. 25.00 taka/MT) throughout the 30 year economic life of the proposed project These additional transfer costs are a disbenefit in the FW project situation.

#### D.9 Homestead Gardens, Agroforestry & Wetland Resources

The proposed project would have substantial positive impacts for homestead gardens and agroforestry resources by offering increased security against flood damage. Under *present* conditions, approximately 98 percent of homestead trees are vulnerable to flood damage. People are presently reluctant to plant tree saplings around their homesteads because of the likelihood of flood damage.

In the flood-prone area, the present annual production for homestead gardens and agro-forestry is approximately Taka 100,000 and Taka 152,000 per hectare respectively. (Table D.10). Survey results indicate annual production from these resources generally increases to about Taka 130,000 and Taka 170,000 in flood-free areas. At the same time, in the FW situation it is expected that 24 hectares of homestead gardens and 2 hectares of agro-forestry resources will be required for construction of the flood control embankment. This is a very real offsetting cost.

In the case of wetland resources, an incremental decrease between the FW and FWO scenarios of Taka 155,300 in 1991 constant economic prices is expected. Decreasing wetland production

appears to be a natural devolution rather than symptomatic of implementation of the Dampara Water Management Project.

The net result is that at project maturity the expected flood protection benefits attributable to homestead gardens, agro-forestry and wetland resources are expected to eventually amount to about Taka 2.2 million per year. This would arise in Year 13; ten years after the flood control measures are in place. These calculations are all summarized in accompanying Table D.10.

# D.10 Economic Analysis

#### D.10.1 Introduction

The economic analysis of a project measures its effect on the economic or allocative efficiency of the whole economy. The economic analysis of a project differs from the financial analysis in the sense that the latter focuses on the money profits accruing to individual farmers, fisherman and firms based on market costs. Rather than market prices, economists use shadow (or efficiency) prices that reflect opportunity costs (i.e., the benefit forgone by using a scarce resource for one purpose instead of its next best alternative use). The economic analysis includes the valuation of externalities wherever practical.

In this project analysis, costs and benefits are identified which arise from the *future with* (FW) project scenario compared to the situation as it would be in the *future without* (FWO) project situation. The difference is the net incremental benefit arising from the project investment. Accordingly, the most basic economic criterion for accepting a project compares the FWO and FW costs and benefits to ensure that the net present value (NPV) of benefits is positive. All incremental benefits and costs are defined as the difference between what would occur in the FWO and FW situations once the project has been implemented.

The economic decision-making criteria employed are Net Present Value (NPV) and Economic Internal Rate of Return which are defined in Section D.2.

#### D.10.2 Rate of Discount

The appropriate discount (or interest) rate reflects the opportunity cost of money to the national economy. The FPCO 'Guidelines for Project Assessment (May 1992) indicates the economic analysis should use a real discount rate of 12 per cent to estimate the net present value(NPV) of the benefit-cost stream. "Real" means excluding inflation. Accordingly, a project with a positive NPV using a 12 per cent discount rate can be considered a viable project and, similarly, a project which is calculated to have an economic internal rate of return in excess of 12 percent would likewise be considered a viable project.

## D.10.3 Period of Analysis

The FPCO 'Guidelines' indicate that planners are to use a 30-year project cycle for the discounting period. Unlike the FPCO Guidelines, the NERP economists have stipulated Year 1 as the initial implementation year rather than Year 0. Gittinger (1982:95) suggests that the discount process used in discounted cash flow analysis implicitly assume that every transaction falls at the end of the accounting period. This is simply accomplished if we consider the initial investment to take place at the end of Year 1 of the project, regardless of whether it will actually take a full year or only a few months.

#### D.10.4 Residual Value

The residual value of the project is generally added to the benefit stream in the last year of the project. It is often taken to be the "resale value" of remaining assets. The residual value of project facilities in the FW situation are ignored in this analysis because their discounted residual value is minimal by the end of the project (i.e., Year 30).

# D.10.5 Land Acquisition Cost

The financial land acquisition cost has not been included in the economic analysis because land taken out of production by the project is, instead, valued in terms of the annual production foregone.

#### D.10.6 Economic Cost-Benefit Stream

The economic cost-benefit stream of the proposed project is given in Table D.11. The cost stream consisting of capital and O&M costs for the proposed project is taken from Section D.4 and Appendix Table 1.

The benefit stream for agriculture has been developed according to text Table D.6. The estimated benefit/disbenefit stream for the fisheries sector has been taken from text Table D.7.

The stream of non-agriculture/fisheries flood damage benefits has been developed by multiplying the annual expected flood damage benefit of Taka 1.94 million, beginning in Year 4, by an annual 3 percent growth factor for Years 5 through 30. (see Table D.9).

The anticipated disbenefit to the navigation sector is assumed to be a constant figure of Taka 23,000 per annum over the 30-year life period of the project. (see Section D.8). The expected benefit stream for Gardens, Agro-Forestry, & Wetland Resources has been constructed assuming that the full benefit will only be achieved at the end of Year 14; climbing approximately 10 per cent per year during the preceding Years 4 through 13 (see Table D.10 for full-benefit estimate).

The projected incremental net benefit stream of the project has been calculated by subtracting the cost stream from the benefit/disbenefit stream.

2

# D.10.7 Net Present Value (NPV) and Economic Internal Rate of Return (EIRR)

The economic NPV of the incremental net benefit stream is equal to:

 $\Sigma$  (Discounted Annual Incremental Benefits) less $\Sigma$ (Discounted Annual Incremental Costs) = B - C = 133.98 million Taka (Table D.11)

This discounted total is about 5 times the size of the initial economic investment. A positive and relatively large NPV estimate indicates that at least from an economic perspective the proposed Dampara Water Management Project appears to be a very feasible investment opportunity.

Similarly, the EIRR is defined as that discount rate (or interest rate) where:

 $\Sigma$ (Discounted Annual Incremental Benefits) =  $\Sigma$ (Discounted Annual Incremental Costs)

That is, that discount rate where B = C.

The imputed EIRR is determined to be about 41.9 % per annum; much higher than the designated "cut-off" rate of 12% per annum (Table D.11). This EIRR estimate once again emphasizes that the DWMP appears to be a very attractive economic investment opportunity.

## D.10.8 Qualifications

Because the estimated NPV & EIRR are relatively high, it is useful to also identify why this is the case. The principal reasons for this are the following:

- Economic costs are relatively low because:
  - the proposed embankment is only on one side (not three);
  - two major drainage structures are already in place (and, thus, a "sunk cost");
  - the design includes virtually no "internal" structure, e.g. roads, bridges and cross-regulators, etc.
- Agricultural benefits, at the same time, may be over-estimated with respect to:
   a) flood damaged area yields;
   b) the extent or rate that cropping patterns will actually shift to HYV rice;
   and/or c) profit margin estimates.

A "worst case" scenario -- the potential downside (if any) to this proposed project -- is simulated in the Sensitivity Analysis conducted immediately following.

## **D.10.9 Sensitivity Analysis**

The economic analysis preceding is based on uncertain future events and imperfect data. Consequently, a sensitivity analysis must be conducted to systematically assess the reliability and robustness of the Base Case estimates calculated in Section D.10.8 above. It is particularly important to identify the benefit and cost items which have the greatest influence on the overall economics of the project, as well as the extent of their influence.

The variables tested in the sensitivity analysis are:

- 1. The inclusion of the costs of two existing drainage structures if they had to be built. This cost is approximately 23 million Taka(1991 Market Price), assumed to have otherwise taken place in Year 2.
- 2. A 20% increase in capital and O&M costs
- 3. The exclusion of all benefits/disbenefits other than crop production benefits
- 4. Yield losses are 50% of Base Case Yields on damaged flood lands
- 5. Full agricultural benefits are achieved in 10 years (rather than 5)
- Costs-of-production are inflated by 20%
- 7. Project implementation is delayed by 2 years

The implications of these changes on the NPV and EIRR are summarized in Table D.12 following:

Table D.12
Summary of Sensitivity Tests

Item	NPV (Taka m. 1991)	EIRR (percent)
BASE CASE	134.0	41.9
1. Sunk Costs Included (Tk 21 m; 1991)	112.7	30.1
2. Capital + O&M Costs Increase 20%	124.2	37.2
3. Exclusion of All Non-Crop Impacts	144.1	52.5
4. Damaged Flood Lands Yield Losses 50%	64.3	28.2
5. Full Ag. Benefits Delayed to 10 Yrs	93.9	29.5
6. Ag. Costs of Production Increase 20%	113.5	38.2
7. Project Implementation Delay by 2 Years	104.0	40.9
WORST CASE SCENARIO (Items 2-6)	30.5	20.3

These simulations highlight the following:

The very economical project design does enhance the EIRR considerably. Assuming the two existing drainage structures where current (rather than sunk) costs, for example, would drop the EIRR from 42%/annum to 30% per annum.

On the other side of the ledger, a similar negative impact would be expected if the projected agricultural benefits were not fully realized for 10 years after construction. The same general impact on the EIRR would be expected if, in fact, flood damaged crop yield losses are being greatly over-estimated.

At the same time, these sensitivities unambiguously highlight the fact that if it wasn't for the negative net impact on fisheries, this project would have an exceptionally high EIRR. In most cases, a positive Net Present Value of something of the order of 100 million Taka (in 1991 terms) should be expected and this would be about four times the cumulative project investment level.

The Worst-Case Scenario suggests that the lowest EIRR that we might expect is 20% per annum; almost double the 12% /annum requirement for project acceptance. A 20% EIRR would correspond to a positive NPV of about 30 million Taka which implies a real rate of return which is still two times the cumulative project investment level over a 30 year time frame.

These sensitivity tests generally reinforce the principal conclusion of the economic analysis conducted in the preceding. (Section D.10.7). That is:

From an economic perspective, the proposed Dampara Water Management Project appears to be a very feasible and relatively low risk investment opportunity for the Government of Bangladesh.

## D.11 Financial Analysis

There are two particularly important financial considerations:

- 1. Financial Impact on Project Beneficiaries
- 2. Financial Impact on Government

## D.11.1 Project Beneficiaries

Potential project beneficiaries in the project area are profiled in Table D.13. The principal project beneficiaries will be these 14,000 households who own cultivated land: small farms of about 1/3<sup>rd</sup> hectare; medium-sized farms which are about 1.5 ha. in size; and larger farms which average about 4 ha. in size. This is their average physical size; with a cropping intensity of about 2.0, the area actually cropped/annum is approximately twice this size. Crop budgets for each of these three farm sizes have been prepared in Appendix Tables 26-27 and summarized in accompanying Table D.14.

Table D.13: Potential Project Beneficiaries

Class	No. of Ho	useholds	Cultivabl Owne		Average Farm Size	Av. Annual HH Income <sup>1</sup>
	No.	%	ha	%	ha	Taka
Landless	7418	34.4	0	0	0	22,371
Small Farms	9466	43.9	2781	22.2	0.3	32,943
Medium Farms	3709	17.2	5686	45.4	1.5	55,491
Large Farms	970	4.5	4058	32.4	4.2	174,977
Total	21563	100%	12525	100%	0.9	42,577
			THE RESERVE OF THE PROPERTY OF THE PARTY OF			NAME OF TAXABLE PARTY OF TAXABLE PARTY.

Kalni-Kushiyara Farm Household Survey.

Source: Dampara Farm Household Survey. (See Social Annex)

These farm budgets highlight the following:

- the proposed project should make a substantial difference to gross farm income (at project maturity), increasing small and medium-sized gross farm income by more than 20 percent;
- the projects' overall impact on total farm family income, however, is a function of how
  dependent they are on the farm as a source of total family income. The largest relative
  impact would be on medium-sized farms (16% increase) while the smallest relative
  impact would be on small farms (7%). Both small and large farms tend to rely more on
  other sources of income for their livelihood:
- incremental gross farm income/person would, at the same time, be highly skewed in favor of larger farmers. This is equally true of the incremental gross farm income/person day estimates. This is because of the relative size of the farms since, on a per-hectare basis, the change would actually be greater for small farmers; and,
- the overall change in the family labor required would be about 5 days/year for small farmers and 14 days/year for middle-sized farmers. It is estimated (see elsewhere) that perhaps 10% of this change would be a female labour requirement.

These estimates consider the cost of 6 month operating capital (at 17.5% interest) but ignore other possible lease, mortgage, or tax payments –all of which can also greatly affect financial well-being in the project area. At least one-third of all households have a land lease arrangement. Rangjoma is a leasing system where the cultivator pays a fixed rent in cash at the time of the contract. The current rate is about Taka 10,000 for single-cropped land and Taka 10,200-10,500 for double-cropped land. Barga is a system of share-cropping where the cultivator and the land-owner share the costs of seed, fertilizers and water equally and divide the output among them equally. Other costs including labour are borne by the cultivator. In addition, bandhak is a traditional mortgage system where land is provided as collateral when money is borrowed. The

lender then holds the right to cultivate the mortgaged land and gets all of the benefits from it until the loan is repaid. If one is not able to repay the loan within a stipulated period, the land is forfeited to the lender.

Although not illustrated in this static farm financial balance sheet, it must be noted that the proposed project will also *reduce income variability* and thus *enhance seasonal food security*. Despite not being quantified, this too is a very real on-farm financial benefit.

## D.11.2 Government Receipts & Expenditures

There are two particular government concerns:

- Cost Recovery Potential
- Net Impact on Foreign Exchange

## Cost Recovery Potential

Potential cost recovery is measured by:

CRI = T/E

where CRI = Cost Recovery Index; T = taxes and other charges on project beneficiaries; and E is project expenditures by government. The two important issues to be addressed when formulating a cost recovery policy are:

- 1) the proportion of the cost expended on a project to be repaid; and,
- 2) the proportion of the benefit received by individuals (which may be far higher than the cost) to be recovered through direct charges or increased taxes.

The financial analysis regarding projected crop production changes suggests that policy-makers could probably introduce a viable cost recovery policy for operation and maintenance of the proposed works. That is, if the additional financial income generated by the project is (say)5,000 Taka per hectare per annum during Years 8-30 (as suggested in Table D.14 above) while the project O&M cost is 1.79 million Taka per year or 146 Taka per hectare of cultivated land, these O&M costs would only amount to about 3 percent of the incremental crop income. Crop farmers with land ownership should have the financial capacity to pay this amount.

## Net Impact on Foreign Exchange

This analysis compares the foreign exchange requirements during project construction with the foreign exchange savings subsequently generated by the project. These savings would largely come from the production of additional food which would otherwise have to be imported.

## D.12 Multi-Criteria Analysis

Finally, the FPCO 'Guidelines describe a methodology for assessing impacts accruing from the proposed DWMP implementation which cannot be based solely on the benefit-cost stream of the financial and economic analyses. Impacts that can only be quantified in physical terms or described qualitatively should also be taken into account in the decision making process. Multi-criteria analysis (MCA) provides a taxonomy and framework for including those impacts in a

concise, standardized and comparable manner.

The MCA framework facilitates a direct comparison of the impacts of a project in economic, financial, quantitative and qualitative terms:

- Economics: Wherever possible, impacts are valued in monetary terms and incorporated into single-valued measures, including the economic internal rate of return (EIRR) and the net present value (NPV). (Section D.10 above)
- Financial Impacts: Considers financial impacts on beneficiaries and government.
   Focuses on income changes to beneficiaries. (Section D.11 above)
- Quantitative Impacts: Considers related parameters such as production, employment, risk, input requirements, etc.
- Qualitative Impacts: Indexes other relevant criteria such as: consistency with government objectives, income distribution, gender, externalities, environmental issues, and other quality-of-life issues. This employs an ordinal ranking, "+10" being the most beneficial impact, "0" being a benign impact, and "-10" being the most severe negative impact.

This is elaborated upon in the 'Main Report', Chapter 9.

7,8,9. FPCO, Guidelines for Project Assessment, Dhaka, 1992

11. Variable costs assumed to have a linear relationship to average yields.

13. Dampara (follow-up) Farm Household Survey.

19. Includes loan interest for short term credit and miscellaneous expenses (see main text).

22. From Dampara(follow up) Farm Household Survey.

23. Assumes excluded grops have the same average gross margin for all farm sizes.
